## USSR/Medicine - Acetylcholine

"Inhibition by Acetylcholine of the Functioning of Skeletal Muscles," V. B. Isachenko, V. M. Karasik, Inst of Expl Med, Acad Med Sci Lab of Gen Pharmacol, USSR

Farm i Toks, Vol 16, No 2, pp 12-15

A. G. Ginetsinskij and N. M. Sharshina had found that intrarterial introduction of acetylcholine during tetanization of a cat's gastrocnemius brings about a pessimal state. V. M. Karasik established that carbacholine (which is not split by cholinesterase) may block completely motor impulses of frogs. The present

254T24

article describes expts carried out in 1950 which prove that acetylcholine inhibits fibrillations brought about in an isolated n. sartorius of the frog by the application of guanidine (I) or of alpha-aminopyridine (II). Hyperkinesia produced by I or II depends on the functional effectiveness of nerve-muscle synapses and therefore [unclear] a cholinergic nature. The differences between various reactions of muscles to acetylcholine (III) added in expts and also liberated as a result of a nerve impulse are due to the fact that other substances besides III are liberated. These differences do not disprove that III acts as a mediator of nerve impulses.

KARASIK, V. M.

"Characteristics of the Toxic Effects Produced by Poisons Which Interfere With Processes of Conjugated Phosphorylation," Farm. i Toks., 16, No.2, pp.59-60, 1953.

The fibrillations which are produced in skeletal muscles under the effect of guanidine, aminopyridine, or tetraethylammonium are briefly intensified and increased in freq as a result of the action of poisons (i.e., dinitrophenol, cyanides, azides, fluorides, nitrites, monobromoacetate, gramicidin, or the antipasteur factor obtained in alkaline hydrolysis of yeast) that interfere with conjugated phosphorylation. After an outburst of fibrillations continuing for 2 - 4 min, a contracture similar to that of rigor mortis took place in expts on tonic muscles.

Rhythmic action of leech muscles caused by veratrine.  
V. M. Karasik and N. A. Koroleva. *Journal of the Soviet  
Biochemical Society*, 1961, No. 1, p. 103-106.

Veratrine (1), even at 0.005 p.p.m.,  
sensitizes leech muscle to K ion; at 0.01 and 0.05 p.p.m. the  
muscle contraction was 2-3 times greater than without L.

At 1 or 2 p.p.m. L stimulates rhythmic muscle action, and  
the effect lasts several hrs. Amplitude of contractions is  
sometimes increased 10-fold. Julian R. Smith

Title : The History of the Concept of the Correlation  
between the Chemical Composition and Structure of  
Drugs and Poisons and Their Action on the Organism.

Orig Pub: Vestn. Akad. med. nauk SSSR, 1957, No 3, 56-60.

**Abstract:** A brief review of the history of the problem,  
beginning with the communication of E. V. Pelikan,  
who first (1854) pointed out that the interaction  
between drugs and the organism is of chemical  
nature. In the further development of the prob-  
lem of correlations between structure and action,  
the author singles out as an important step the  
publication of R. Buchheim of his system of drugs

Card 1/3

Abstract: (1856) and the resulting realization of a new system based on the establishment of a relationship between therapeutic agents and materials peculiar to the organism with similar structure and chemical behavior. The author also stressed the investigations which demonstrated visible correlation between the chemical properties of drugs and their pharmacological and toxic effects in connection with problems of purposeful synthesis of drugs. (Brown and Frazier, 1869.) The greatest successes in these fields were achieved following the discovery of many biologically active compounds and the establishment of their chemical structure. The slow progress in the synthesis of therapeutic antidotes is particularly stressed, despite the fact that the synthetic

**Abstract:** chemist finds himself in a most favorable position, since it is easier for him than for the pharmacologist to foresee the possibility of these or other reactions between poisons and other compounds. Important, more recent successes in this field are mentioned briefly (BAL and other mercapto-compounds, ethyl-endiaminetetra-acetic acid). The effectiveness of some mercapto-compounds in the treatment of diseases in whose etiology toxic agents play a role is underlined. -- A. G. Brusilovskaya

Title : Antiferromagnetism of Anhydrous Sulphates  $\text{Ni}^{2+}$ ,  $\text{Fe}^{2+}$ ,  
 $\text{Co}^{2+}$ ,  $\text{Cu}^{2+}$ .

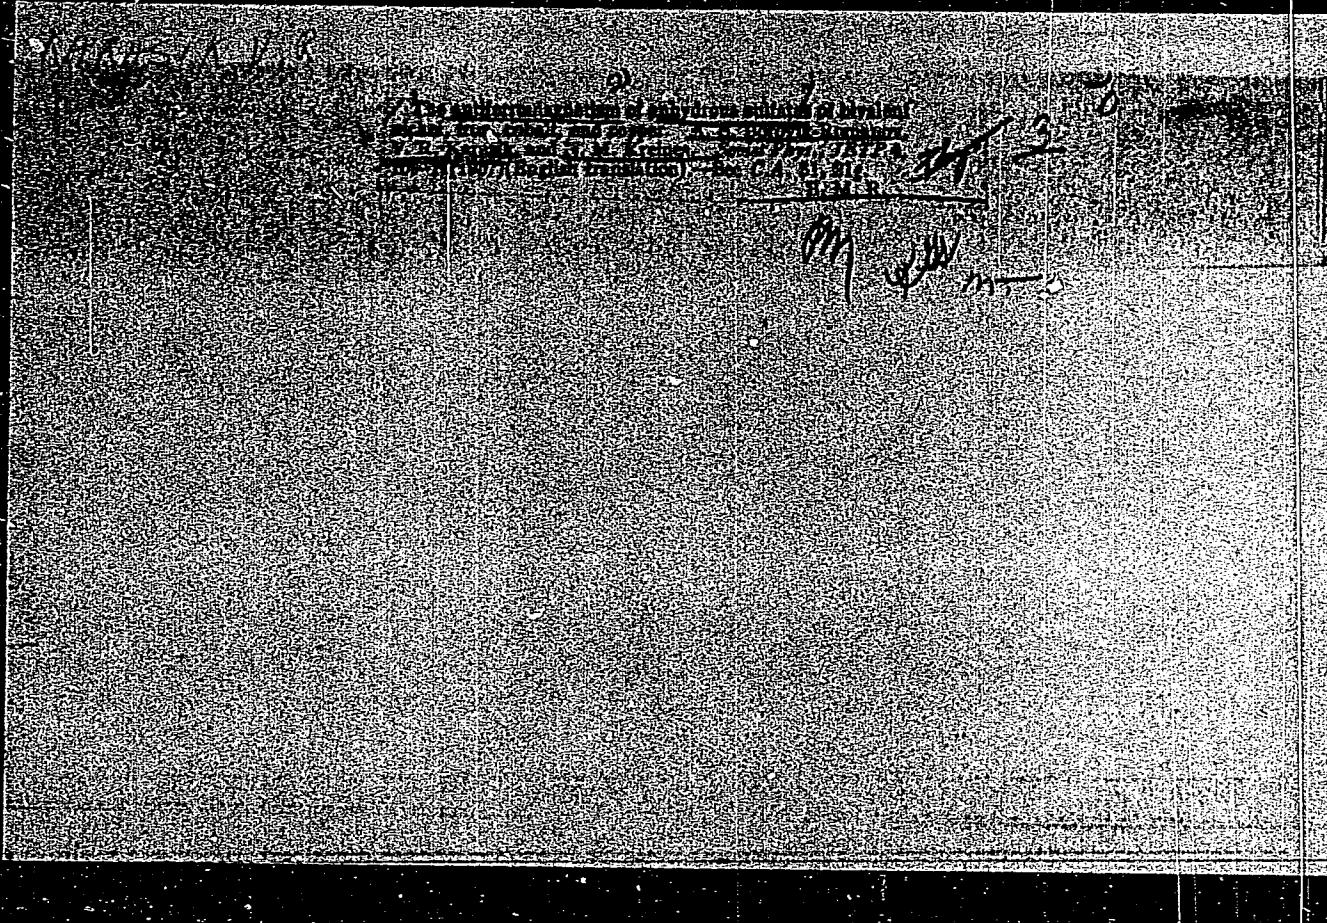

Orig Pub : Zh. eksperim. i teor. fiziki, 1956, 31, No 18-24

Abstract : The temperature dependence of the magnetic susceptibility of anhydrous sulphates  $\text{NiSO}_4$ ,  $\text{FeSO}_4$ ,  $\text{CoSO}_4$ , and  $\text{CuSO}_4$  was investigated between 12 and 300° K. It is shown that  $\text{NiSO}_4$ ,  $\text{FeSO}_4$ , and  $\text{CoSO}_4$  change into the antiferromagnetic state at temperatures  $T_c$  that are respectively 37, 21, and 15.5° K. Above  $T_c$  one observes for  $\text{SO}_4$  and  $\text{FeSO}_4$  only a slight deviation from the Curie-Weiss law. On the other

TITLE: An Apparatus for the Production of Strong Magnetic Fields of Short Duration (Ustanovka dlya polucheniya kratkovremennykh sil'nykh magnitnykh poley)

PERIODICAL: Pribory i tekhnika eksperimenta, 1959, Nr 1, pp 142-145  
(USSR)

ABSTRACT: An apparatus is described in which fields of  $3 \times 10^5$  oersted can be produced in a volume of 0.7 l. The field is obtained by a discharge of a bank of condensers. The discharge is oscillatory and has a period of  $2 \times 10^{-4}$  sec. The apparatus is similar to that described by Foner and Kolm (Ref 2), Furth and Wanek (Ref 3) and Piekara and Malecki (Ref 12). The solenoid employed is described in some detail and the field distribution along its axis is shown in Fig 6. For a solenoid 30 mm long and 11 mm in diameter the field is uniform along an axis 7 mm long to an accuracy of 3%. The energy consumption per

TITLE: The Concentration Effect in Germanium

PERIODICAL: Fizika tverdogo tela, 1960, Vol. 2, №. 10, pp. 2594 - 2595

TEXT: From the quantum theory it is known that, if the concentration of the carriers depends on temperature, this concentration depends also on the magnetic field. In agreement herewith, the Hall constant increases exponentially with an increasing magnetic field. This effect is called the concentration effect. From the experimentally determined dependence of the Hall constant of Ge on the magnetic field at 20.4°K, which is shown in Fig. 1, it may be seen that up to a field strength of roughly 90 kiloersteds, the Hall constant remains constant. From 90 to 250 kiloersteds, the Hall constant rises to double its value. Fig. 2 shows the transverse magnetic resistance of a sample as a function of the magnetic field. Above a field strength of 90 kiloersteds, this resistance does not increase linearly. Fig. 3 shows the reciprocal mobility as a function

B019/B056

of the magnetic field for the same experimental conditions. Also here a change in the dependence may be observed at 90 kiloersteds. Investigations carried out at 77°K showed that up to 250,000 oersteds the Hall constant does not depend on the magnetic field. Particular attention is drawn to the fact that at 20.4°K the dependence of the Hall constant on the magnetic field is linear above 90 kiloersteds and not exponential. This is due to the fact that the carrier concentration is only a weak function of temperature. There are 3 figures and 7 references:

TITLE: Investigation of the Hall Effect and Transverse Magnetic  
Reluctance of Germanium in a Field of up to 400 Kilocersteds

PERIODICAL: Doklady Akademii nauk SSSR, 1960, Vol 130, Nr 3, pp 521 - 522  
(USSR)

ABSTRACT: The apparatus used here has already been described in an earlier paper by the author (Ref 1). The author studied single germanium crystals grown along the [111] axis. The resistivity of the anti-mony-alloyed n-type samples was 3 ohms.cm at room temperature for a diffusion length of 0.7 mm. The p-type samples had about the same resistivity (diffusion length of 1.7 mm). For the purpose of investigating the Hall effect the author used plates of 4.2°1.4°1.4 - 0.8 mm or crosses with a distance of 4.2 mm between the current- and the Hall contacts. The n-type samples had tin contacts and the p-type samples indium contacts. A compensation technique was employed for emf measurement. It was assumed that the shape of the samples and the condition of their surface had no influence on the measurement. In order to avoid even effects, the Hall emf was measured with four differently

Card 1/3

oriented magnetic fields and currents. In measuring magnetic reluctance the author neglected the Hall component by commutation of the current direction. The power produced by the measuring current in the sample did not exceed 0.01 w. The samples were immersed into liquid hydrogen or nitrogen. Figure 1a illustrates the results of investigations of the Hall effect at 77°K. The slight change in slope which was found in all n-type and p-type samples, corresponds to a change of the Hall constant by 15%. Figure 1b shows typical results of measurement of the Hall effect at 20.4°K. In all cases it was found that there was a linear relation between the Hall emf and the magnetic field. Figure 2 contains results of investigation of the transverse magnetic reluctance, which are inconsistent with theory (Refs 2 and 3). The author thanks A. I. Shal'nikov for his interest in the present paper and for his valuable advice. He further thanks V. L. Bonch-Bruyevich and A. E. Yunovich for a discussion of the results, and G. B. Kurganov for his assistance in measurements. There are 2 figures and 3 Soviet references.

TITLE: An inductively excited super-conducting magnet

PERIODICAL: Pribory i tekhnika eksperimenta, no.2, 1962, 179-180

TEXT: The magnet has a solid Armco iron core 6 cm long, 4.5 cm wide and 1 x 1 cm cross-section. The pole tip diameter is 5 mm and the gap length 3 mm. The two 6 cm outer diameter spools for the magnetizing coils of brass, each contains an inner niobium ring of 16 mm inner dia and 22 mm outer dia, 3 mm wide, over which is wound a copper coil of 8000 turns of 8 micron dia wire which, at a temperature of 4.2°K has a resistance of about 30 ohms. The magnet hangs in a cryostat on a stainless steel tube. At the temperature of liquid nitrogen the magnetization curve is linear up to a current of 300 mA at which the magnetic field is 20 kilo-oersted (as measured by a test coil in the gap). The niobium is magnetized by applying current to the copper coil at a temperature slightly above 9°K, the magnet is then immersed in liquid helium and after about 90 sec it becomes superconducting and the current is switched off. With a magnetizing current of

TITLE: A solenoid of a superconducting alloy

PERIODICAL: Akademiya nauk SSSR. Vestnik, <sup>32</sup> no. 5, 1962, 86-87

TEXT: The ductility of a niobium-zirconium alloy was increased by thermo-mechanical treatment. A solenoid (inside diameter, 4 mm; outside diameter, 2.5 cm) made from highly superconductive drawn wires was used for creating a magnetic field of 35,000 oe at the temperature of liquid helium where the superconductivity of the alloy (25 % zirconium) vanished in a magnetic field of 80,000 oe. The superconductive solenoid is a low-capacity accumulator of magnetic energy. 3 liters of liquid helium is consumed per month. The solenoid costs 5,000 rubles. There are 2 figures.

TITLE: Effect of microheterogeneity on the characteristics of superconductivity of Nb-Zr-Ta alloy

SOURCE: Fizika metallov i metallovedeniye, v. 21, no. 3, 1966, 379-383

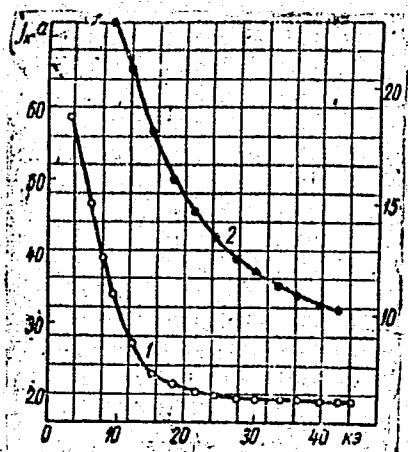

TOPIC TAGS: niobium alloy, zirconium containing alloy, tantalum containing alloy, superconductive alloy, alloy structure, alloy superconductivity

ABSTRACT: In a search for new superconducting materials, a niobium-base alloy containing 35% zirconium and 15% tantalum has been tested for the effect of structural microheterogeneity on the magnitude of critical current density. Two alloy ingots were melted in an electron-beam furnace and cooled at different rates. The slowly cooled ingot had a homogeneous structure and a resistivity of 49.9 pohm·cm. In the rapidly cooled ingots the dendrites were niobium- and tantalum-rich and the matrix was zirconium-rich; the resistivity of this ingot was 54.4 pohm·cm. Both ingots were conditioned by machining to a diameter of 4 mm, preforged, and cold drawn into wire 0.2 mm in diameter. The size of Card 1/3

109TOPIC TAGS: superconductivity, superconducting alloy, niobium alloy, zirconium  
containing alloy, solenoid / S-60 solenoid, S-50 solenoid, B-3 solenoid, B-solenoidABSTRACT: Superconducting solenoids for creating high magnetic fields are discussed.  
A brief historical review is presented of the development of superconducting solenoids  
and of the use of niobium-zirconium alloys. Three equivalent circuits for a  
superconducting solenoid connected with a power supply are presented and discussed.  
Some of the physical problems of superconducting niobium-zirconium alloy solenoids  
and the means of overcoming them are given. The construction and properties of four  
superconducting solenoids (S-60, S-50, B-3, and B-1) are described. The solenoids  
are wound with 0.25-mm diameter wire of 75% Nb—25% Zr alloy which is

Card 1/2

L 38539-66

ACC NR: AT6014758

10

electrolytically coated with a  $20 \mu$  thick layer of copper. The fields attainable with these solenoids range up to 46 koe. Two of the solenoids (S-50 and B-1) were used together to produce a field of  $51\frac{1}{2}$  koe. The schematic for a 6-V transistorized power supply, which is current-regulated in the range 0.2-75 a, is given. The authors thank B. M. Vul, corresponding member AN SSSR, for valuable advice; Ye. M. Savitskiy, V. V. Baron, M. B. Golant, I. A. Baranov, and R. S. Shmulevich for supplying the wire for fabricating the solenoids; G. T. Nikitina, V. I. Sarychev, G. I. Agapov, and I. A. Bocharov for help in the work. Orig. art. has: 4 equations, 3 tables, and 3 diagrams.

117

TOPIC TAGS: superconducting alloy, niobium containing alloy, titanium containing  
alloy, solenoid, wire

ABSTRACT: The construction and testing of solenoids wound with superconducting wire  
of Ni - 50% (by wt) Ti alloy are described. The first solenoid, consisting of 12 369  
turns of the 0.2-mm diameter wire wound on a 10.4-mm diameter tube, reached a field  
of 14.0 koe with a maximum current of 5.7a or a current density of  $1.8 \times 10^4$  a/cm<sup>2</sup>  
(at 4.2K). The solenoid was unwound and the wire was galvanically coated with a 50  $\mu$   
thick copper layer and insulated with Aquadag. It was found that copper plating  
significantly embrittled the wire, possibly because of hydrogen diffusion and the

Card 1/2

L 36123-66

ACC NR: AT6014760

formation of titanium hydride.<sup>1</sup> The wire was rewound on the same form, producing a second solenoid of 9109 turns. The maximum current for this solenoid was 6.8a or a current density of  $2.2 \times 10^4$  a/cm<sup>2</sup> (also at 4.2K). However, the field reached only 11.4 koe due to a reduced filling factor. The obtained results agree well with published data for short samples of the Ni<sup>21</sup>Ti alloy. The authors thank B. N. Vul, corresponding member AN SSSR, and M. B. Golant, doctor of technical sciences, for their interest in the work and valuable advice. Orig. art. has: 2 figures.

TITLE: Procedure for measuring the critical parameters of superconductors for alternating current

911

SOURCE: Soveshchaniye po metallovedeniyu i metallofizike sverkhprovodnikov. 1st, 1964. Metallovedeniye i metallofizika sverkhprovodnikov (Metallography and physics of metals in superconductors); trudy sovushchaniya. Moscow, Izd-vo Nauka, 1965, 130-131

TOPIC TAGS: superconductivity, critical current, alternating current, superconducting alloy, solenoid, CURRENT DENSITY, EXTERNAL MAGNETIC FIELD

ABSTRACT: The instrumentation and experimental procedure are described for measuring the critical current at 140 khz and its dependence on the fixed external magnetic field of wire specimens of 50% Nb, 50% Zr alloy. The specimen is wound on a Teflon form and is connected as the coil in an LC circuit. For some voltage across the circuit the current through the specimen reaches the critical value, and a sharp voltage drop is observed. A superconducting solenoid, described in a preceding article (V. R. Karasik et al. Present compilation, p. 101), is used to create the external magnetic field. The measured dependence of the critical current density at 140 khz on the magnetic field for a 150  $\mu$  diameter specimen is presented

graphically. It is noted that no dependence of the critical current density on the wire specimen diameter (in the range 150--230  $\mu$ ) was observed. Utilization of measurements of the quality factor of the LC circuit by the method of free oscillation attenuation is also described. The authors thank B. M. Vul, corresponding member AN SSSR, for interest in the work. Orig. art. has: 2 equations and 3 figures.

TITLE: Influence of the metal-semiconductor boundary on the electrical characteristics of transistors

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy,  
Radiotekhnika, v. 5, no. 2, 1963, 265 - 268

TEXT: The system considered is illustrated in Fig. 1a. This is a p-n-p-m transistor where m is a metal. The influence of the metal-semiconductor boundary was investigated for the following metals: pure Pb and pure Sn (having work-functions of 4.15 and 4.51 eV), In and a Pb-Sn alloy. The experimental transistors were based on p-type Ge having a resistivity of 10-<sup>2</sup> cm, which resulted in high collector voltages and large pulse currents. The work function of all the metals was lower than that of Ge, so that potential barriers of different heights could be obtained at the metal-semiconductor boundary. The experimental samples were prepared by the double-diffusion method and the area of the emitter junction was 0.12 mm<sup>2</sup>. The forward and reverse characteristics for the metal-semiconductor

boundaries were plotted experimentally. Also, the current gain as a function of the emitter current for the transistor operating in the common-base circuit was measured for all the metals (Pb, Sn, In and the alloy). It was found from this that the gain could be greater than unity and increased with reduction of the height of the potential barrier. The switch-on current of the transistors was also measured and it was found that this was about 2 mA in the case of Sn but 4 mA for the alloy and much greater in the case of transistors with a Pb metal boundary. As regards the pulse current, it was found that, other conditions being equal, this increased with decreasing potential barrier. There are 6 figures.

TOPIC TAGS: pn junction, epitaxial junction, ~~Ga~~ semiconductor, germanium

ABSTRACT: P-n junctions obtained by epitaxial building up of single-crystal p-Ge on an n-Ge backing were investigated. The junction thickness was determined by means of an oblique cut of  $1^{\circ}$ , with either a thermal probe or visually (by electrolytic etching in a 10% KOH solution). A square-law relation between the charge capacitance and the bias voltage, which corresponded to an abrupt junction, was observed. The I-V characteristics measured within +25 -196°C revealed considerable reverse currents even at a low negative bias which may be associated with a high density of structural defects in both the film and the backing. The forward-current vs. bias-voltage plot is exponential,  $I \approx \exp(qv/\beta kT)$ ;  $\beta = 6$  at 20°C. At voltages 0.7—0.75 v, an inversion of forward-current vs. temperature relation was observed which agrees with the theory of p-n junction at high injection levels.
